Chemistry 4000
Introduction to Inorganic Chemistry: The Different Perspectives of Bonding

## Problem Set \#1 Answer Key

## Introduction-

1. An appropriate pentadentate ligand will be accepted. A pentadentate ligand is one that can coordinate a metal at five different atoms/sites.
2. pH influences the M-L interactions. In this particular demonstration, at lower pH one or two of the ligands coordinated with the metal. At higher pH , three of the ligands saturated the coordination sites of the metal. Recall that both of these metal ions "prefer" a coordination number of 6 .

## Chapter 1-

1. 

radial nodes $=\mathrm{n}-\mathrm{l}-1$
angular nodes $=1$

| Nodes | 3s | $\mathbf{4 p}$ | 3d | 5f |
| :---: | :---: | :---: | :---: | :---: |
| Radial | 2 | 2 | 0 | 1 |
| Angular | 0 | 1 | 2 | 3 |

2.a. $\mathrm{Ti}^{3+}:[\mathrm{Ar}] 3 \mathrm{~d}^{1}, 1$ unpaired $\mathrm{e}^{-}$
2.b. $\mathrm{Mn}^{2+}:[\mathrm{Ar}] 3 \mathrm{~d}^{5}, 5$ unpaired $\mathrm{e}^{-}$
2.c. $\mathrm{Cu}^{2+}:[\mathrm{Ar}] 3 \mathrm{~d}^{9}, 1$ unpaired e-
2.d. $\mathrm{Gd}^{3+}:[\mathrm{Xe}] 4 \mathrm{f}^{7}, 7$ unpaired $\mathrm{e}^{-}$
3.a
$3 \mathrm{p}:\left(1 \mathrm{~s}^{2}\right)\left(2 \mathrm{~s}^{2}, 2 \mathrm{p}^{6}\right)\left(3 \mathrm{~s}^{2}, 3 \mathrm{p}^{3}\right)$
$S=0.35(4)+0.85(8)+1(2)=10.2$
$Z^{*}=Z-S=15-10.2=4.8$

## 3.b

4s: $\left(1 s^{2}\right)\left(2 s^{2}, 2 p^{6}\right)\left(3 s^{2}, 3 p^{6}\right)\left(3 d^{7}\right)\left(4 s^{2}\right)$
$\mathrm{S}=0.35(1)+0.85(15)+1(10)=23.10$
$Z^{*}=Z-S=27-23.10=3.9$
3.c

3d: $\left(1 s^{2}\right)\left(2 s^{2}, 2 p^{6}\right)\left(3 s^{2}, 3 p^{6}\right)\left(3 d^{5}\right)$
$S=0.35(4)+1(18)=19.40$
$Z^{*}=Z-S=25-19.40=5.60$
3.d
$3 \mathrm{~s}:\left(1 \mathrm{~s}^{2}\right)\left(2 \mathrm{~s}^{2}, 2 p^{6}\right)\left(3 s^{2}\right)$

$$
\begin{aligned}
& S=0.35(1)+0.85(8)+1(2)=9.15 \\
& Z^{*}=Z-S=12-9.15=2.82
\end{aligned}
$$

## 4. Book problems

1.1

|  | ${ }_{20}^{50} \mathrm{Cr}$ | ${ }_{24}^{52} \mathrm{Cr}$ | ${ }_{24}^{53} \mathrm{Cr}$ | ${ }_{24}^{54} \mathrm{Cr}$ |
| :---: | :---: | :---: | :---: | :---: |
| Proton | 24 | 24 | 24 | 24 |
| Electron | 24 | 24 | 24 | 24 |
| Neutron | 26 | 28 | 29 | 30 |

$50-Z=50-24=26$

## 1.9

$1 \mathrm{~m}=10^{9} \mathrm{~nm}, \bar{v}=R\left(\frac{1}{2^{2}}-\frac{1}{n^{2}}\right)=\frac{1}{\lambda}$
$\lambda=\left(R\left(\frac{1}{2^{2}}-\frac{1}{n^{2}}\right) 10^{-9}\right)^{-1} \Rightarrow n=2 \sqrt{\frac{1}{-1\left(\left(\lambda^{-1}\left(10^{9}\right) \frac{1}{R}\right)-\frac{1}{2^{2}}\right)}}$

| $\boldsymbol{\lambda}$ (nm) | $\mathbf{n}$ |
| :--- | :--- |
| 656.28 | 3 |
| 486.13 | 4 |
| 434.05 | 5 |
| 410.17 | 6 |

1.20.a. The wave function value for the $\mathrm{He}^{+}$will differ of the H due to its Z value, so the plot of $R(r)$ would be shifted to the left.
1.20.b.

The probability of finding an $e^{-}$close to the nucleus is higher.
1.34.a. The first ionization state tends to be relatively low and decrease while going down the periodic table due to the shielding effect and the probability of being further away from the nucleus.
1.34.b. Ionization energy for Al and downward is lower than B because the core electrons shield the valence electrons. This trend does not continue because of the poor shielding $d$ and $f$ orbitals.
1.34.c. The trend seems constant until atoms Mn and Zn . In the case of Mn , the electron removal is from the filled 4 s orbital. For Zn the 4 s 3 d are fully filled.
1.34.d. The trend is an increase in $\mathrm{Z}^{*}$. It is more difficult to ionize N than O because of the partial stability of the half-filled $p$ orbitals.
1.34.e. Xe being a noble gas would need a high amount of energy to remove an electron from a fully occupied orbital. This energy is higher than that of Cs, which has a half filled s orbital.
1.34.f. Same logic as part e applies, $P$ has a half-filled orbital stability.
1.40.a. See problem 1.34.e
1.40.b. While adding the first electron to $O$, the atom needs to liberate energy to accept the first electron but while adding the second electron, it feels the negative charge making a repulsion therefore making the negatively charged atom in need of energy to accept the second electron to overcome the repulsion.
1.40.c. The third electron would occupy the 2 s instead of the $2 p$ orbital because the 2 s is a lower energy system as it is capable of penetrating the 1 s orbital more than the $2 p$.
1.45.a. No other lines fall in the visible region of the electromagnetic radiation spectrum. You also may have weak emission lines. Also maybe some excited states are populated.
1.45.b. $v=\frac{c}{\lambda}=5.09 \times 10^{14} s^{-1}$
1.45.c. Once electrons are excited a photon emission of a specific energy can be released returning the electrons to the ground state.

## Chapter 2-

## 1. Book problems

2.8. VB theory is better applied when taking in consideration atoms in the ground state. For $\mathrm{Ne}_{2}$ to be under this theory there would have to be a missing electron per atom and energy would have to be applied for this. This theory does not make this molecule viable. Each Ne already has a filled octet.
2.14 .

|  | Isoelectronic | Valence electrons |
| :---: | :---: | :---: |
| $\mathrm{F}_{2}$ | $\left[\mathrm{O}_{2}\right]^{2-}$ | $\mathrm{Cl}_{2}$ |
| $\mathrm{NH}_{3}$ | $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$ |  |
| $\left[\mathrm{GaBr}_{4}\right]^{-}$ |  | $\mathrm{SiBr}_{4},\left[\mathrm{GaCl}_{4}\right]^{-}$ |
| $[\mathrm{SH}]^{-}$ |  | $[\mathrm{OH}]^{-}$ |
| $\left[\mathrm{BH}_{4}\right]^{-}$ | $\left[\mathrm{NH}_{4}\right]^{+}$ |  |
| $\left[\mathrm{AsF}_{6}\right]^{-}$ | $\mathrm{SeF}_{6}$ |  |
| $\left[\mathrm{PBr}_{4}\right]^{+}$ | $\mathrm{SiBr}_{4}$ | $\left[\mathrm{GaCl}_{4}\right]^{-}$ |
| HF | $[\mathrm{OH}]^{-}$ |  |

2.25.
a. Due to the two isotopes of $\mathrm{Br}\left({ }^{79} \mathrm{Br},{ }^{81} \mathrm{Br}\right) \mathrm{Br}_{2}$ coexist as $\left.\left({ }^{79} \mathrm{Br}\right)\right)_{2},\left({ }^{81} \mathrm{Br}\right)_{2}$ and $\left({ }^{79} \mathrm{Br}^{81} \mathrm{Br}\right)$ therefore the MS spectrum peak of $\mathrm{Br}_{2}{ }^{+}$can be $m / z=158,162$ or 160 .
b. $\mathrm{Br}-\mathrm{Br}$ intramolecular distance is 227pm and 331pm is the intermolecular distance.
c. Organizing an MO diagram for $\mathrm{Br}_{2}$ and $\mathrm{Br}_{2}{ }^{+}$, in the $\mathrm{Br}_{2}{ }^{+}$, the electron is removed from an antibonding orbital making a higher bond order
2.26.

a. Preference is due to less steric hindrance for the $\mathrm{CH}_{3}$ in the equatorial position (there being more spare, $120^{\circ}$ vs. $90^{\circ}$ ) and because in VSEPR model the more electronegative ligands occupy axial positions.
